

Table 1: Conditional finite-screen identification bounds

Population and quantity	N	K_+	K_-	U	Lower	Upper
Screen: nominal membership	158	61	0	97	38.61%	100.00%
Screen: positive-label correctness	158	61	0	97	38.61%	100.00%
Screen: no reference overlap	97	0	0	97	0.00%	100.00%
Candidate: nominal membership	67	0	0	67	0.00%	100.00%
Candidate: positive-label correctness	57	0	0	57	0.00%	100.00%
Candidate: no direct event	10	0	0	10	0.00%	100.00%

Notes: K_+ and K_- count retained reference labels establishing membership and nonmembership; $U = N - K_+ - K_-$ counts unknown outcomes. The bounds are K_+/N and $(K_+ + U)/N$. Selected post-hoc overlap concordance is 61/61, reported separately. The author report covers 94 unchanged reference labels, not candidate outcomes. All bounds condition on each linked reference outcome being valid for the corresponding screen issuer/event. Issuer matching does not prove event/time alignment or independent same-event pairing. No sampling or missingness model is imposed; these are neither confidence intervals nor performance-validation estimates. Scope exclusions and no-direct-event flags are not coded as negative outcomes. The finite issuer screen is not a population of verified eligible exits, and the candidate remains a proposal pending final freeze and human coding.
